

# International Association of Economic and Social Councils and Similar Institutions (AICESIS)

55<sup>th</sup> Session of the Commission on the Status of Women  
New York, ... 2011

Statement by the International Association of Economic and Social Councils and Similar Institutions (AICESIS), delivered by Mrs Paola Manacorda, Member of the Italian National Council for Economic and Labor (CNEL)

1. My name is Paola Manacorda, I am a member of the Italian Economic and Social Council (CNEL) and I am speaking on behalf of the International Association of Economic and Social Councils and Similar Institutions (AICESIS) created 10 years ago by 27 countries which today includes more than 50 institutions from Africa, Latin America, Asia and Europe, plus 8 new membership applications. The principal goals of AICESIS are to promote dialogue, exchange experiences and best practices between members, promote the establishment of Economic and Social Councils in the world, to promote the use of social dialogue and participative governance in order to reconcile economic development, environmental sustainability and social equity. The members of AICESIS are autonomous advisory assemblies with national competence made of organizations representing "social partners" (employers, trade unions) and other components of civil society (farmers, craftsmen, NGOs, independent experts, etc.) constituting a representation of economic and social interests.

2. Moving in the direction shown by Resolution no. 2009/15 of the Economic and Social Council, the 55<sup>th</sup> Session of the Commission on the Status of Women gives us an important opportunity to reflect on women's and young women's access to and participation in education, with special reference to scientific education, and also to assess the relative impact on job levels and on so-called "gender work". We know that education is a driver of economic growth and social justice, and its importance in achieving gender equality is universally acknowledged. Despite this fact, in 2007 72 million children in the world did not have access to primary education, 54% of whom girls. In the same way, 54% of 71 million adolescents that did not attend Science, technology and innovation not only improve productivity and competitiveness, contributing to economic growth, but also, if used correctly, can help to fight against poverty, protect human health and the environment and aid food security. Some major nations have understood this importance and are taking the action.

3. Many countries have devoted big resources to research and scientific development and to scientific and technical education for young people in these countries.

<sup>1</sup> UNESCO, *Reaching the Marginalized, Education for All Global Monitoring Report 2010*, p. 2.  
<sup>2</sup> UNESCO, cit.

... devoted to education, which is devoted to scientific education. The result of these efforts is an increase of GDP and of new products in sectors like biotechnologies, medicine, electronics, automotive, space, pharmaceutical sectors. In all of these countries there is a strong correlation between public economic growth.

The same can't be told for Europe, where the percentage of public spending for education is less than 10% and the continuous cuts to the public spending in education has affected mainly the science-based faculties.

Therefore, Europe, mainly in Modern and EU Europe, scientific education for young women is hardly affected by this declining trend.

The state's strict education is reflected in an economy that continues to take on a limited number of qualified workers, and it works to the detriment of women workers. In the European countries, the participation rate and relative employment rate are systematically lower than for men: in 2009 the average percentage of women employed in the main countries of Mediterranean Europe was approximately 53%, compared with 71. % for men.<sup>3</sup>

There has been a rise in their percentage of small enterprises (even though concentrated in micro and small enterprises, with many operating in the informal economy). The growth of these enterprises are able to develop, acquire or apply technology depends on the availability of qualified human resources, good structures and the general regulatory context.

In many countries, and even in many innovative enterprises, there is still a gender pay gap, while becoming professional and family life is still not a priority in political agendas.

Furthermore, as a result of the financial and economic crisis between 2008 and 2009 the female unemployment rate was greater than that of men in some regions: Southern Asia (10% vis-à-vis 5.5%), Latin America and the Caribbean (11.1% vis-à-vis 6.9%), the Middle East and North Africa (15% vis-à-vis 8.1%), and developed economies (8.6% vis-à-vis 8.2%)<sup>4</sup>

When efforts have been made at an international level to show that science, technology and innovation are closely linked to the issue of gender equality, the two areas continue to be perceived as separate problems.

It should rather be considered that an essential role of education, and scientific education in particular, is its ability to increase not only the possibility of obtaining decent work but also democratic participation, and contribute to human development, allowing individuals – both men and women – to take informed decisions on critical aspects of their life, including their health. To achieve this goal, it is obviously necessary to first raise the participation of girls in primary and secondary school education. It may be particularly important in this sense to increase the number of primary school teachers training a scientific background, as these are the first to introduce science to children. Compared with boys, girls would appear to be less attracted (according to some empirical researches) to scientific studies, and thus to technological professions. Progress has been made in this respect, in "higher education": with women now taking part in some specific sectors of science, in particular in life sciences. Despite everything, women continue to be under-represented in the areas of information technology and engineering. Comparing the

data available for 121 countries it may be seen, for instance, that women make up 29% of researchers, while only 15% of countries have attained gender parity. In order to help girls develop a greater familiarity with science and technology, and arouse their interest in related topics, as well as eradicate the career-leaving bias still beleaguering society, these issues need to be put forcefully to the attention of primary actors, such as Governments and Parliaments, Universities and research centers, social partners.

5. Economic and Social Councils and similar institutions, as addressed institutionally, delegated to foster dialogue among social partners and as advisory bodies of Governments and Parliaments, can play an important role in raising awareness among Governments and various bodies, suggesting measures such as:

- a. **Devote** adequate public financing to scientific and technological training programs, extended to every pay group as possible in order to set up a critical mass of scientists and technologists that can conduct business research and implement productive applications in many different sectors, also using long-life learning initiatives, necessary to catch the rapid changes in technology and scientific knowledge.
- b. **Suggest** specific programs to ensure that women have fair access to scientific and technological training, and **promote** awareness-building actions, also through the mass media, to encourage women to pursue scientific careers.
- c. **Get** scientific organizations to guarantee gender equilibrium when selecting for the top positions of responsibility, and take women's needs into account when organizing research work, as well as ensure that research contents and methods take into account the needs and interests of women.
- d. **Suggest** that high visibility be devoted to women scientists, also promoting their visits in secondary schools.
- e. **Stress** the need and the importance to be highlighted in statistics of scientific research, innovation and employment.

As far as dialogue among non-State partners is concerned, UNESCO and similar Institutions can contribute through:

- f. Carefully monitor the placement and career promotion of women in scientific circles, disseminating and promoting best practices.
- g. **Push** high-technologies companies to hire and turn to account the contribution of women, also with reference to the elimination of any pay-gap.
- h. Assess, through statistical data and empirical researches, the effect of the adequate technical-scientific training of women on their employability and current employment.
- i. Jointly promote specific projects recognizing professional and family life, taking into account the commitment needed to perform scientific and technological work.
- j. Support the creation of female entrepreneurs in the scientific and technical sectors, tapping into local resources having a scientific background, so that women can become an increasingly important part of the business world.

date available for 121 countries.<sup>2</sup> 23% of researchers, while only 15% of countries have attained gender equality.<sup>3</sup> In order to help girls develop their skills with science and technology, we urge their interest in related topics, as well as eradicate the stereotypes still prevailing in society, these issues need to be put forcefully to the attention of many actors, such as Governments and Parliaments, Universities and research centers, social partners.

2. Economic and Social Councils and similar institutions, as bodies institutionally delegated to foster dialogue among all stakeholders, can play an important role in raising an awareness among Governments and Parliaments, suggesting measures such as:

- a. Devote adequate public financing to scientific and technological training programs, extended to as many people as possible, in order to build up a critical mass of scientists and technologists that can conduct basic research and implement productive applications in many different sectors, also using long-life learning initiatives, necessary due to the rapid obsolescence of technical and scientific knowledge.
- b. Suggest specific programs to ensure that women have fair access to scientific and technological training, and promote awareness-building actions, also through the mass media, to encourage women to pursue scientific careers.
- c. Get scientific organizations to guarantee gender equilibrium when selecting for positions of responsibility, and ensure that research contents and organizing research work, as well as ensure that research contents and methods take into account the needs and interests of women.
- d. Suggest that high visibility positions in research institutions, and particularly their visits in secondary schools.
- e. Stress the need for the female component to be highlighted in statistics on scientific research, innovation and employment.

As far as dialogue among social partners is concerned, ESCs and similar institutions can contribute through:

- f. Carefully monitor the placement and career promotion of women in scientific circles, discerning and promoting best practices.
- g. Push high-technologies companies to hire and turn to account the contribution of women, also with reference to the elimination of any pay-gap.
- h. Assist, through statistical data and empirical research, the effect of the adequate technical-scientific training of women on their employability and current employment.
- i. Jointly promote specific projects reconciling professional and family life, taking into account the commitment needed to perform scientific and technological work.
- j. Support the creation of female entrepreneurship in the scientific and technical sectors, tapping into local resources, promoting scientific background, so that women can become an increasingly important part of the business world.
